

C2 Structural validity is a boundary, not semantic correctness

Enforced by the declared interface

Operation name from declared candidates

Target / field from the supported schema

Argument shape and value types

Complete output before call construction

Requires separate checks

Did we choose the intended operation?

Do parameter values satisfy the task?

Is the action authorized in this environment?

Does execution produce the intended effect?

Observed example: `ensure_ascii=False` is structurally valid, but does not reject NaN.
